1.0 Introduction

Injection orientation of supercritical CO\textsubscript{2} (SCO\textsubscript{2}) during enhanced gas recovery (EGR) and sequestration is one of the key factors to the overall technique in terms of displacement efficiency and extent of gas mixing. Injection orientation plays a vital role in the behaviour of SCO\textsubscript{2} as it traverses the pore spaces of the porous medium during CH\textsubscript{4} displacement at reservoir conditions under gravity. However, the rate of mixing between the injected CO\textsubscript{2} and the displaced CH\textsubscript{4} appeared more rapid in the horizontal injection orientation compared to that of vertical injection from previous laboratory tests.

This study aims to investigate the flow behaviour of SCO\textsubscript{2} in a rock core under gravity using a numerical method. The modelling was used to evaluate the gravity effect on the efficiency of CH\textsubscript{4} displacement by mimicking a laboratory experimental approach.

2.0 Methodology

2.1 Model assumptions and governing equations
1. CO\textsubscript{2} density \(\rho\) and viscosity \(\mu\) are constant
2. Interstitial velocity \(u\) is constant
3. Porosity \(\phi\) and Permeability \(k\) both of with are assumed constant.
4. Dispersion is also assumed to be isotropic throughout the displacement process.
5. Flow is compressible.
6. Temperature is also assumed to be constant.

\[\rho \frac{\partial \mathbf{u}}{\partial t} = \nabla \cdot (\rho \mathbf{u} \mathbf{u}) + \nabla \cdot (\rho \mathbf{u} \nabla \psi) = -\nabla P + \frac{1}{\rho} \left[ (\nabla \rho \cdot \mathbf{u}) - \frac{2}{3} (\nabla \cdot \mathbf{u}) \right] - \frac{1}{\rho} \left( \mu \nabla^2 \mathbf{u} + \beta \mathbf{u} + \frac{Q_m}{\varepsilon^2} \right) - \mathbf{F} + \rho g \] (1)

\[\frac{\partial \mathbf{u}}{\partial t} = \nabla \cdot (\rho \mathbf{u} \mathbf{u}) + \nabla \cdot (\rho \mathbf{u} \nabla \psi) = -\nabla P + \frac{1}{\rho} \left[ (\nabla \rho \cdot \mathbf{u}) - \frac{2}{3} (\nabla \cdot \mathbf{u}) \right] - \frac{1}{\rho} \left( \mu \nabla^2 \mathbf{u} + \beta \mathbf{u} + \frac{Q_m}{\varepsilon^2} \right) + \rho g \] (2)

2.3.1 Brinkman Equation

2.3.2 Transport of concentrated species

\[\frac{\partial (\rho \text{C}_i\mathbf{u}_i)}{\partial t} + \nabla \cdot (\rho \text{C}_i\mathbf{u}_i \mathbf{u}) = R_i\] (3)

Modelling in Nuclear Science and Engineering Seminar 2020 4/5

3.0 Results
The results show that gravity contributes significantly to the excessive mixing between CO₂ and CH₄ during the displacement process in the horizontal orientation as it sinks to the bottom of the porous media along the longitudinal axis of the porous medium. This is attributed to the density of the SCO₂ in relation to that of CH₄ at those conditions.

4.0 Conclusion
The numerical results demonstrated a conceivable representation of the laboratory experimental trend obtained for the concentration profiles of CO₂ as it displaced the CH₄. This study explains the reason behind the observation of early breakthrough of CO₂ in the horizontal orientation and subsequent higher mixing between CO₂ and CH₄ compared to the vertical orientation injection.
